GAP, QPA / QPA2, Catreps, CAP, homalg_project

3 Introduction in category theory

This section serves two purposes: On the one hand, it is an introduction to quivers and category theory. On the other hand it introduces concrete categories which we want to represent, and all the additional constructions that are needed to that goal.

3.1 Quivers

In this section, we first want to define the category **Quiv** and how it is the prototype for the category **Cats**. In order to describe the category **Quiv** of quivers, we first have to define what a category is and for this we need the definition of a quiver. Lateron we will revisit this definition as we can define quivers as the objects in the quiver category **Quiv**.

Definition 3.1.1. (Quiver)
A directed graph or quiver q consists of a class of objects (or vertices) $q_0 = \mathrm{Obj}\, q$ and a class of morphisms (or arrows) $q_1 = \mathrm{Mor}\, q$ together with two defining maps

$$s, t : q_1 \rightrightarrows q_0$$

s called source and t called target.

In the next definition we are giving a new characterization for q_1 by looking at all arrows between two fixed objects.

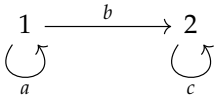
Definition 3.1.2. (Hom-set of a (locally) small quiver)

(1) Given two objects $M, N \in q_0$ we write $\mathrm{Hom}_q(M,N)$ or $q(M,N)$ for the fiber $(s,t)^{-1}(\{(M,N)\})$ of the product map $(s,t) : q_1 \longrightarrow q_0 \times q_0$ over the pair $(M,N) \in q_0 \times q_0$. This is the class of all morphisms with source $= M$ and target $= N$. We indicate this by writing $\varphi : M \longrightarrow N$ or $M \xrightarrow{\varphi} N$. Hence q_1 is the disjoint union $\dot{\bigcup}_{M,N \in q_0} \mathrm{Hom}_q(M,N) = q_1$. As usual we define $\mathrm{End}_q(M) := \mathrm{Hom}_q(M,M)$.

(2) If the class $\mathrm{Hom}_q(M,N)$ is a set for all pairs (M,N) then we call the quiver locally small. We therefore talk about Hom-sets. If additionally, q_0 is a set, then the quiver is called small.

(3) A quiver with a finite set of objects and a finite set of morphisms is called a finite quiver.

Example 3.1.3. (Quiver with 2 objects and 3 morphisms)



The objects of this quiver q are $q_0 = \{1,2\}$, and the morphisms are $q_1 = \{a,b,c\}$ with
$s(a) = 1 = t(a)$, $s(c) = 2 = t(c)$ and $s(b) = 1, t(b) = 2$.
Thus $\mathrm{End}_q(1) = \{a\}, \mathrm{End}_q(2) = \{c\}$ and $\mathrm{Hom}_q(1,2) = \{b\}$ whereas $\mathrm{Hom}_q(2,1) = \varnothing$.

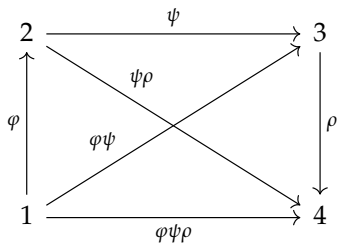
In `QPA` this quiver is encoded as `q(2)[a:1->1,b:1->2,c:2->2]` where the first `(2)` in parentheses stands for the total number of objects.

Definition 3.1.4. (Composable arrows; path in a quiver)
Since we already have the source and target maps, we say two arrows $a, b \in q_1$ are composable if $t(a) = s(b)$ or $t(b) = s(a)$. In this case we can write a sequence of composable arrows $p = a_1 a_2 \cdots a_n$ where $t(a_i) = s(a_{i+1})$ for $i = 1, \ldots, n-1$. We call this sequence a path from $s(a_1)$ to $t(a_n)$ and the integer $n \in \mathbb{Z}_{\geq 0}$ the length $l(p)$ of the path p. Although it's not an arrow, we can define the source and target of a path $p = a_1 \cdots a_n$ as $s(p) := s(a_1)$ and $t(p) := t(a_n)$. A path $p = a_1 \cdots a_n$ with $s(a_1) = t(a_n)$, i.e. $s(p) = t(p)$, is called cyclic.
For an endomorphism $a \in \mathrm{End}_q(M)$ we write a^n for $aa \cdots a$ (n times). In the case of $n = 0$ an empty path whose source and target are the vertex $i \in q_0$ is called the trivial path at i and is denoted e_i. Note that the composition of paths $e_i e_i$ has length zero starting at i therefore $e_i^2 = e_i$.

Lemma 3.1.5. *Let Q be a quiver. If there is a path of length at least $|Q_0|$, then there are cyclic paths, and thus infinitely many paths.[2]*

Proof. Assume that there exists a path of length greater or equal to $|Q_0|$. Then there exists a path of length $n = |Q_0|$, say $\alpha_1 \cdots \alpha_n$. Consider the vertices $x_i = s(\alpha_i)$ for $1 \leq i \leq n$ and $x_{n+1} = t(\alpha_n)$. Then these are $n+1$ vertices, thus there has to exist $i < j$ with $x_i = x_j$. Let $\omega = \alpha_i \cdots \alpha_{j-1}$, this is a path with source and target $x_i = x_j$, thus a cyclic path. But then ω^m is a path for any natural number m. The path ω has length $j - i \geq 1$, thus ω^m has length $m(j-i)$. This shows that these paths are pairwise different. □

Example 3.1.6. (A quiver with no cycles)



The longest path $1 \to 2 \to 3 \to 4$ has length 3. If after the object 4 another arrow would go to either $1, 2, 3$ or 4 itself, we would have a cyclic path and thus infinitely many paths.

3.2 Categories

Definition 3.2.1. (Category)
A category $\mathcal{C}$ is a quiver with two further maps:

(id) The identity map $1_{(\,)}$ mapping every object $X \in \mathcal{C}_0$ to its identity morphism 1_X:

$$\mathcal{C}_0 \xrightarrow{1} \mathcal{C}_1$$

(μ) And for any two composable morphisms φ and $\psi \in \mathcal{C}_1$, i.e. with $t(\varphi) = s(\psi)$, the composition map μ, which maps $\varphi, \psi \in \mathcal{C}_1 \times \mathcal{C}_1$ to $\mu(\varphi, \psi) \in \mathcal{C}_1$ which we also write as $\varphi\psi$.

$$\mathcal{C}_1 \times \mathcal{C}_1 \xrightarrow{\mu} \mathcal{C}_1$$

The defining properties for 1 and μ are:

(1) $s(1_M) = M = t(1_M)$, i.e.
$1_M \in \mathrm{End}_{\mathcal{C}} \, \forall M \in \mathcal{C}$.

(2) $s(\varphi\psi) = s(\varphi)$ and
$t(\varphi\psi) = t(\psi)$
for all composable morphisms $\varphi, \psi \in \mathcal{C}$.

$$\mu : \mathrm{Hom}_{\mathcal{C}}(M, L) \times \mathrm{Hom}_{\mathcal{C}}(L, N) \longrightarrow \mathrm{Hom}_{\mathcal{C}}(M, N)$$

(3) $(\varphi\psi)\rho = \varphi(\psi\rho)$ [associativity of composition]

(4) $1_{s(\varphi)}\varphi = \varphi = \varphi 1_{t(\varphi)}$ [unit property]
The identity is a left and right unit of the composition.

3.3 Functors

Categories are themselves objects in the category of categories, which leads to a question: What is a morphism between categories?

Definition 3.3.1. (Functor)
A functor $F : \mathcal{C} \to \mathcal{D}$, between categories $\mathcal{C}$ and $\mathcal{D}$, consists of the following data:

- An object $Fc \in \mathcal{D}_0$, for each object $c \in \mathcal{C}_0$.
- A morphism $Ff : Fc \to Fc' \in \mathcal{D}_1$, for each morphism $f : c \to c' \in \mathcal{C}_1$, so that the domain and codomain of Ff are, respectively, equal to F applied to the domain or codomain of f.

The assignments are required to satisfy the following two functoriality axioms:

- For any composable pair $f, g \in \mathcal{C}_1, Fg \cdot Ff = F(g \cdot f)$.
- For each object $c \in \mathcal{C}_0, F(1_c) = 1_{Fc}$.

Put concisely, a functor consists of a mapping on objects and a mapping on morphisms that preserves all of the structure of a category, namely domains and codomains, composition, and identities.

3.4 Natural transformations

With fixed categories $\mathcal{C}$ and $\mathcal{D}$ we can consider functors $F, G \in \mathrm{Hom}(\mathcal{C}, \mathcal{D})$ themselves as objects in the category $\mathrm{Hom}(\mathcal{C}, \mathcal{D})$ of functors between $\mathcal{C}$ and $\mathcal{D}$. In this functor category, the morphisms between two functors are called natural transformations.

Definition 3.4.1. (Natural transformations)
Given categories $\mathcal{C}$ and $\mathcal{D}$ and functors $F : \mathcal{C} \to \mathcal{D}$ and $G : \mathcal{C} \to \mathcal{D}$, a natural transformation $\alpha : F \Rightarrow G$ consists of:

- an arrow $\alpha_c : Fc \to Gc \in \mathcal{D}_1$ for each object $c \in \mathcal{C}_0$, the collection of which define the components of the natural transformation, so that, for any morphism $f : c \to c' \in \mathcal{C}_1$, the following square of morphisms in $\mathcal{D}$

$$\begin{array}{ccc} Fc & \xrightarrow{\alpha_c} & Gc \\ \downarrow{\scriptstyle Ff} & & \downarrow{\scriptstyle Gf} \\ Fc' & \xrightarrow{\alpha_{c'}} & Gc' \end{array}$$

  commutes, i.e., has a a common composite $Fc \to Gc' \in \mathcal{D}_1$.

4 Finite concrete categories

Definition 4.0.1. (Finite and concrete categories)

(1) A finite category is a category with a finite set of objects and a finite set of morphisms.

(2) A concrete category is a category whose objects have underlying sets and whose morphisms are functions between these underlying sets. Otherwise it's called an abstract category.

Clearly every finite category is a small category.

As we have seen in the previous section, a quiver q with a path of length greater than $|q_0|$ must have loops and is thus infinite. We will construct finite concrete categories by paying attention that the arrows between different objects are only one-directional, thus we have a partial order on the set of objects.

The following algorithm takes two integers n and m as arguments and gives a finite concrete category as output with n objects which are each FinSets with m elements. The generating endomorphisms are each a permutation of order m, while the non-endomorphisms are bijective mappings from each object $c \in \mathcal{C}_0$ to all later objects $c' \in \mathcal{C}, c' > c$ with the obvious order.

```

5 The categories Quiv, Cat, FinSets, k-Mat, CatReps and the Functor Category

In this section, we first want to define the category **Quiv** and how it is the prototype for the category **Cats**. We want to restrict ourselves to finite concrete categories, which brings us to the category **FinSets**. Our goal is to represent concrete categories, for this we need the source and target categories of our representations. The source category is **k-Algebroids** which we compute algorithmically from a concrete category. The target category of our category representations is **k-Mat**. The category where our category representations lie in is **CatReps** for which we show that it's a subcategory of the **Functor Category**.

5.1 Additional structure on the Hom-set of a category

Example 5.1.1. A group G defines a category BG with a single object. The group elements are its morphisms, which are all automorphisms of the single object. The identity element $e \in G$ acts as the identity morphism for the unique object in this category. The hom-set of that category is itself a group.

This example can be generalized to categories where the hom-set is a ring or an R-algebra. But for this we need a commutative ring R and thus the category R-Mod.

Definition 5.1.2. Ab-Category An Ab-category is a category in which all homomorphism sets are abelian groups. That means in addition to the composition of morphisms $\mu : \mathcal{C}_1 \times \mathcal{C}_1 \longrightarrow \mathcal{C}_1$ we have another binary operation $+ : \mathcal{C}_1 \times \mathcal{C}_1 \longrightarrow \mathcal{C}_1$, that distributes over the composition, i.e.

$$\mu(f+g,h) = \mu(f,h) + \mu(g,h)$$

.

The concept of a functor is central in category theory. It is how the objects and morphisms of two categories relate to one another.

Definition 5.1.3. (Functor)
In the category **Cat** which has categories as objects, functors are the morphisms between these objects. Let $\mathcal{C}, \mathcal{D} \in \mathrm{Obj}\,\mathbf{Cat}$ be categories. A functor $F : \mathcal{C} \longrightarrow \mathcal{D}$ between $\mathcal{C}$ and $\mathcal{D}$ consists of the following data:

(1) For every object $c \in \mathcal{C}_0$ there is an object $Fc \in \mathcal{D}$.

(2) For every morphism $f \in \mathcal{C}_1$, i.e. $c \xrightarrow{f} c'$ there is a morphism $Ff \in \mathcal{D}_1$ with $Fc \xrightarrow{Ff} Fc'$, i.e. $s(Ff) = F\,s(f)$ and $t(Ff) = F\,t(f)$

Functors are compatible with the identity map and the composition map:

(3) For every object $c \in \mathcal{C}_0$ we have $1_c \in \mathcal{C}_1$ and for the functor F we demand that $F\,1_c = 1_{Fc} \in \mathcal{D}_1$.

(4) For every pair of morphisms $f, g \in \mathcal{C}_1$ with $t(f) = s(g)$ we have $fg \in \mathcal{C}_1$ and we demand that $Fg\,Fg = F\,gf$.

With the definition of a category and the category of functors finished, we can come back and use them to define the category of quivers **Quiv**.

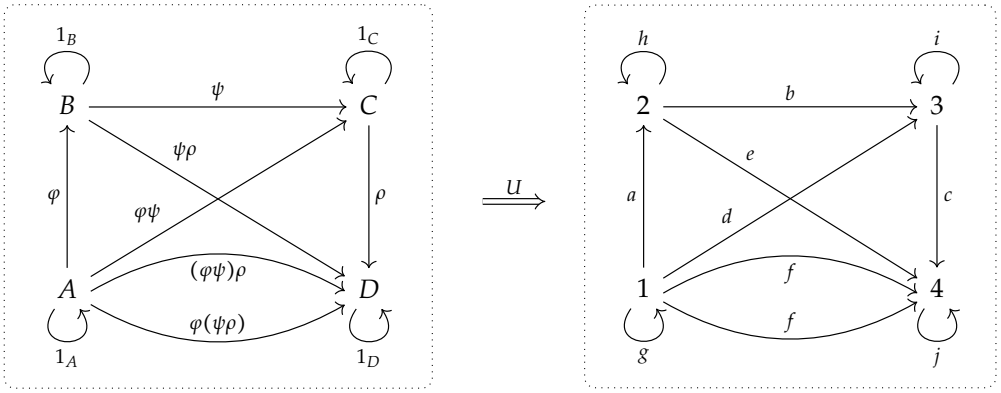
Definition 5.1.4. (The category **Quiv**)[3] Let the Kronecker category $\mathcal{K}$ be the category with two objects, 0 and 1, and two non-identity morphisms, s and t $1 \overset{s}{\underset{t}{\rightrightarrows}} 0$. Let **FinSets** be the category of finite sets with morphisms being maps between those sets. The category of quivers **Quiv** is the category of functors from $\mathcal{K}$ to **FinSets**. For a quiver $q \in \mathrm{Obj}\,\mathbf{Quiv}$ we write q_x for the image of $x \in \{0,1\}$ under q. The images under q of the morphisms s and t are again denoted by s and t.

As we have seen, every category is a quiver, but in general, to become a category, a quiver is lacking identity morphisms and the composition of morphisms. To be more precise, there is a functor U from the category of categories CAT to the category of quivers Quiv, called the underlying quiver or forgetful functor.

$$\mathrm{Cat} \xrightarrow{\quad U \quad} \mathrm{Quiv}$$

mapping every object $M \in \mathcal{C}_0$ to the same objects in q_0, mapping every arrow $\varphi \in \mathcal{C}_1$ to an arrow $a \in q_1$, respecting source and target, but forgetting the special role of the identity morphisms and of the composition morphisms.

Example 5.1.5. (Underlying quiver)



In the category on the left, associativity of composition guaranteed that $(\varphi\psi)\rho = \varphi(\psi\rho)$, so those two arrows were already the same, so they are mapped to the same arrow $f = U((\varphi\psi)\rho) = U(\varphi(\psi\rho))$ in the quiver on the right. We didn't have to draw both arrows for f, but since they are equal, there is still only one arrow in the hom-set $\mathrm{Hom}_q(1,4) = \{f, f\} = \{f\}$.
All the other identities are not preserved under the forgetful functor, e.g. d doesn't know what it has to do with a and b apart from $s(d) = s(a)$ and $t(d) = t(b)$. Especially the former identity arrows are now just endomorphisms with no defining property.
The paths g^2f, gf and fj^3 are all different, while in the category, they all simplify to $1_A 1_A(\varphi\psi)\rho = 1_A(\varphi\psi)\rho = (\varphi\psi)\rho 1_D 1_D 1_D = (\varphi\psi)\rho$ due to the unit property and associativity.

Definition 5.1.6. (Ab-category) An Ab-category is a category in which all homomorphism sets are abelian groups, and composition distributes over addition.
In other words, A category $\mathcal{C}$ is an Ab-category if for every pair of objects $M, N \in \mathcal{C}_0$, $(\mathrm{Hom}_{\mathcal{C}}(M,N), +)$ is an abelian group (with the neutral element called zero morphism), and for all morphisms $\gamma, \delta \in \mathrm{Hom}_{\mathcal{C}}(M,N), \alpha, \beta \in \mathrm{Hom}_{\mathcal{C}}(N,L)$

$$(\gamma + \delta)\alpha = \gamma\alpha + \delta\alpha \text{ and}$$

$$\gamma(\alpha + \beta) = \gamma\alpha + \gamma\beta.$$

Note that every hom-set has its own unique zero morphism. E.g. in $\mathrm{Mat}_{\mathbb{Q}}$ the 2-by-3 zero-matrix $0 \in \mathrm{Hom}(2,3)$ is different from the 4-by-4 zero-matrix $0 \in \mathrm{Hom}(4,4)$.

Example 6.1.2. (Forgetful functor) bla

Definition 6.1.3. (full functor; faithful functor)

6.2 Natural transformations are morphisms between functors

7 Yoneda's Lemma: Completion and cocompletion of a category

7.1 Embedding categories

Lemma 7.1.1. *(Yoneda's Lemma)*

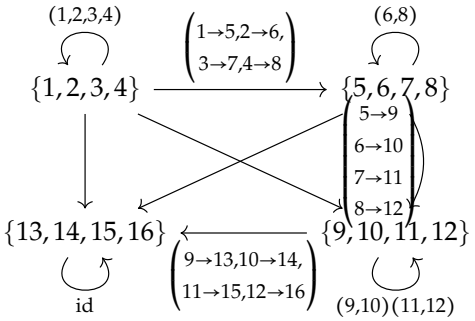
Proof. □

Projective objects?

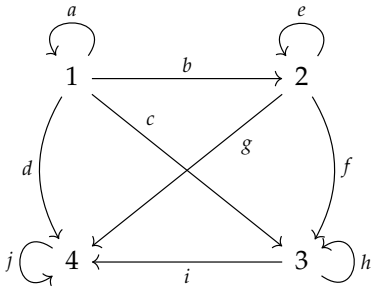
$$(1\quad 2\quad 3\quad 4)\begin{pmatrix}1\to 5, & 2\to 6\\ 3\to 7, & 4\to 8\end{pmatrix}(6\quad 8)\begin{pmatrix}5\to 9\\ 6\to 10\\ 7\to 11\\ 8\to 12\end{pmatrix}(9\quad 10)(11\quad 12)\begin{pmatrix}9\to 13, & 10\to 14\\ 11\to 15 & 12\to 16\end{pmatrix}\mathrm{id}$$

7.2 Yoneda Projective

Consider the concrete category



and its $\mathbb{K}$-Algebroid kq



together with the relations

$$[a^4-(1), e^2-(2), h^2-(3), j^1-(4), bf-c, bef-ach, bg-d, ci-d, achi-beg, a^3beg-chi, fi-g]$$

The resulting category algebra has dimension 43.

We can look at the submodule of the category algebra consisting of all arrows starting at `kq.1`. This is what the function `YonedaProjective( CatReps, kq.1 )` gives us:

```
proj1 := YonedaProjective( CatReps, kq.1 ); <(1)->4, (2)->8, (3)->8, (4)->8; (a)->4x4,
(b)->4x8, (c)->4x8, (d)->4x8, (e)->8x8, (f)->8x8, (g)->8x8, (h)->8x8, (i)->8x8, (4)->8x8>
```

The number 4 associated with object (1) tells us that the submodule of all arrows starting and ending at (1) has dimension 4. Its basis is the set of paths $\{a, a^2, a^3, a^4 = (1)\}$.

Likewise in

```
proj4 := YonedaProjective( CatReps, kq.4 ); <(1)->0, (2)->0, (3)->0, (4)->1; (a)->0x0,
(b)->0x0, (c)->0x0, (d)->0x1, (e)->0x0, (f)->0x0, (g)->0x1, (h)->0x0, (i)->0x1, (4)->1x1>
```

The submodule of all arrows starting at (4) is only of dimension 1, since it's already the identity arrow $\{j = (4)\}$.

Dimension of the (quotient of the) path algebra is 43. Sum of all dimensions of the yoneda projectives on each objects is 43.

Definition 7.2.1. (Yoneda projective) Yoneda's projective representation given by the object o is the submodule of the category algebra consisting of all arrows starting at o.

Conjecture:
Dimension of the path algebra = Sum of dimensions of the yoneda projectives on each object.
What does the yoneda projective mean???
Function that creates examples for concrete categories so that I can check my conjecture.

Algorithm 2: `RightQuiverFromConcreteCategory`

Input : a finite concrete category C with n objects
Output : the right quiver $q(n)$

let Obj be the set of objects of C;
let $n := Length(Obj)$;
let $gMor$ be the set of generating morphisms of C;
let A be the empty set and let $i := 1$;
foreach *morphism mor in gMor* **do**
    let $A_{i,1}$ be the position of $Source(mor)$ in Obj;
    let $A_{i,2}$ be the position of $Range(mor)$ in Obj;
    let $i := i + 1$;
end
let q be the right quiver with vertices $\{1, \ldots, n\}$ and arrows A.
return q;

Algorithm 3: `RelationsOfEndomorphisms`

Input: a commutative ring k and a finite concrete category C
Output: the endomorphism relations of the category C

let $q :=$ `RightQuiverFromConcreteCategory`(C);
let kq be the path algebra generated by k and q;
let $gMor$ be the set of generating morphisms of C;
let $A := Arrows(q)$;
let *relsEndo* be the empty set;
foreach $i = 1, \ldots, Length(gMor)$ **do**
    let $mor := gMor_i$
    if *mor is not an endomorphism* **then**
        continue;
    end
    let $m := 0$ and let *powers* be the empty set;
    let $foundEqual$ be false;
    while $mor^m \notin powers$ **do**
        let $n := 1$;
        while $\neg foundEqual$ **do**
            if $mor^{(m+n)} = mor^m$ **then**
                Add the relation $kq.(A_i)^{(m+n)} - kq.(A_i)^m$ to relsEndo;
                foundEqual := true;
            end
            n := n+1;
        end
        Add mor^m to powers;
        m := m+1;
    end
end
return *relsEndo*;

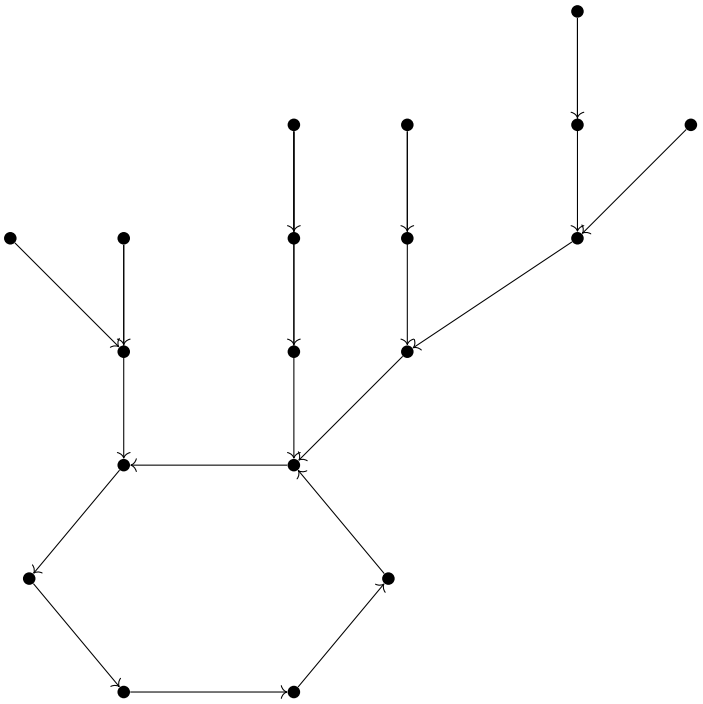
Algorithm 4: `Algebroid`

Input: a commutative ring k and a finite concrete category C
Output: the k-linear closure of the category C over the commutative ring k

return;

10 Relations of the Algebroid

10.1 Relations of endomorphisms



Lemma 10.1.1 (σ-Lemma)**.** *Let $\mathcal{C}$ be a finite concrete category. Then for each object $M \in \mathcal{C}_0$ the set $\mathrm{End}_{\mathcal{C}}(M)$ is a monoid and for each endomorphism $f \in \mathrm{End}_{\mathcal{C}}(M)$ there exist $m, n \in \mathbb{N}$ such that $f^{(m+n)} = f^m$. If $m = 0$ and $n \geq 1$ then f is bijective with $f^{-1} = f^{n-1}$.*

Proof. The properties of a monoid are precisely the associativity of composition and the unit property from 3 and 4. Since $\left|\mathrm{End}_{\mathcal{C}}(M)\right| < \infty$ there are only finitely many endomorphisms $f_1, \ldots, f_N \in \mathrm{End}_{\mathcal{C}}(M)$. Let $\{f^k | k \in \mathbb{N}\} \subset \mathrm{End}_{\mathcal{C}}(M)$, i.e. there is a function $\{f^k | k \in \mathbb{N}\} \to \{f_j | j \in \{1, \ldots, N\}\}; f^k \mapsto f_j$ not necessarily surjective and by the pigeonhole principle highly non injective, since $|\mathbb{N}| > \left|\mathrm{End}_{\mathcal{C}}(M)\right|$. □

Groupoid: A small category in which every morphism is an isomorphism.
Algebroid
EmbeddingOfSumOfImages
What is an Algebroid? Bialgebroid?

12 Additive Category

13 Abelian Category

14 The Category of Categories

15 The Categories of Functors

16 The Representation of a Category

17 Representation

Grundidee von FunctorCategory
Standard-Monoidale Struktur von der Zielkategorie z.B. TensorUnit(C)

18 Algorithms

```
60      AddInverse( C,
61        function( alpha )
62          return Inverse( UnderlyingCell( alpha ) ) / CapCategory( alpha );
63      end );
64
```

```

```

Algorithm 5: `RightQuiverFromConcreteCategory`

Input : a finite concrete category C with n objects
Output : the right quiver $q(n)$

1 let Obj be the set of objects of C;
2 let $n := Length(Obj)$;
3 let $gMor$ be the set of generating morphisms of C;
4 let A be the empty set and let $i := 1$;
5 **foreach** *morphism mor in gMor* **do**
6 | let $A_{i,1}$ be the position of $Source(mor)$ in Obj;
7 | let $A_{i,2}$ be the position of $Range(mor)$ in Obj;
8 | let $i := i + 1$;
9 **end**
10 let q be the right quiver with vertices $\{1, \ldots, n\}$ and arrows A.
11 **return** q;

We want the endomorphism relations so that the path algebra is finite-dimensional and we get a finite Gröbner basis.

Proof that algorithm is correct Proof that it terminates.

Wir haben BasisOfExternalHom benutzt um Decompose in CAP umzusetzen um EmbeddingOfSubRepresentation umzusetzen um WeakDirectSumDecomposition umzusetzen.

Algorithm 6: `RelationsOfEndomorphisms`

Input: a commutative ring k and a finite concrete category C
Output: the endomorphism relations of the category C

```
1  let q := RightQuiverFromConcreteCategory(C);
2  let kq be the path algebra generated by k and q;
3  let gMor be the set of generating morphisms of C;
4  let A := Arrows(q);
5  let relsEndo be the empty set;
6  foreach i = 1,...,Length(gMor) do
7      let mor := gMor_i if mor is not an endomorphism then
8          continue;
9      end
10     let m := 0 and let powers be the empty set;
11     let foundEqual be false;
12     while mor^m ∉ powers do
13         let n := 1;
14         while ¬foundEqual do
15             if mor^(m+n) = mor^m then
16                 Add the relation kq.(A_i)^(m+n) – kq.(A_i)^m to relsEndo;
17                 foundEqual := true;
18             end
19             n := n+1;
20         end
21         Add mor^m to powers;
22         m := m+1;
23     end
24 end
25 return relsEndo;
```
